-CHEATS -Ruby on Rails

https://pragmaticstudio.com

Create a New Rails App

rails new app_name

creates a new Rails application with a given name

example: rails new events

rails server (or rails s)

starts a web server on http://localhost:3000

rails console (or rails c)

starts a Rails console session

bundle install

installs all required gems and their dependencies

code.

opens the Visual Studio Code editor for the current working directory

ERb Tags

%> runs the Ruby code and **substitutes** result into template

<%

%> runs the Ruby code but **does not substitute** result into template

```
    </l
```

Create a Controller Class

rails generate (or g) controller name_of_controller

creates a controller with the given name

example: rails g controller events

* controller names are always **plural**

rails destroy controller name_of_controller

cleans up what got generated

example: rails destroy controller events

Create a Model and Migration

rails g model name_of_model field:type field:type...

creates a model with the given name and a migration for creating a database table with the specified fields (columns) and types

example: rails g model event name:string location:string price:decimal

* model names are always **singular**

Migrations

rails g migration name_of_migration field:type field:type...

creates a migration with a given name along with the specified fields and types

example: rails g migration AddFieldsToEvents starts_at:datetime description:text

tip: Name using the convention AddXXXToYYY to add the specified columns to the YYY table

rails db:migrate

runs any pending migration files in the db/migrate directory

rails db:migrate:status

checks the status of all migrations

rails db:rollback

reverses the last applied migration

rails db:migrate VERSION=XXXX

rolls back to any previous migration version

Common Migration Methods

```
create_table(name, options={}) do |t|
  t.column_type :column_name, options...
end
creates a new table and adds column definitions
change_table(table_name, options = {})
uses a block to change columns in the table
drop_table(name)
drops the table
rename_table(table_name, new_name)
renames a table
add_column(table_name, column_name, type, options = {})
adds a new column to the table
remove_column(table_name, column_name)
removes the column from the table
```

Column Types

:binary

:boolean

:date

:datetime

:decimal

:float

:integer

:primary_key

:string

:text

:time

:timestamp

Common Migration Methods (cont.)

```
change_column(table_name, column_name, type, options = {})
```

changes the column's definition according to the options

rename_column(table_name, column_name, new_column_name)

renames a column in the table

add_index(table_name, column_name, options = {})

adds a new index to the table

remove_index(table_name, options = {})

removes the given index from the table

execute(sql)

executes arbitrary SQL statements

Common Tasks

rails -T

see a list of all tasks

rails -T db

see a list of only the database-specific tasks

rails routes

see a list of all defined routes

rails db:seed

loads the seed data defined in db/seeds.rb

rails db:reset

drops and re-creates the database, applies all migrations, and loads the seed data defined in db/seeds.rb

Generate a Resource

rails g resource name_of_resource field:type field:type.....

generates a resource with the given name along with fields and types

example: rails g resource registration name:string email:string how_heard:string event:references

generates:

- a migration for creating the registrations database table
- a Registration model with a belongs_to declaration
- an empty RegistrationsController
- a set of resource routes

Define Resource Routes

resources : name_of_resource

dynamically defines all the routes for a resource

example: resources :events

generates: 8 defined routes

Helper	HTTP Verb	URL Pattern	Controller#Action	
events_path	GET	/events	events#index	
event_path	GET	/events/:id	events#show	
edit_event_path	GET	/events/:id/edit	events#edit	
	PATCH	/events/:id	events#update	
	PUT	/events/:id	events#update	
	POST	/events	events#create	
new_event_path	GET	/events/new	events#new	
	DELETE	/events/:id	events#destroy	

REST vs. SQL Actions

Actions	show	create	update	destroy
SQL	select	create	update	delete
REST	get	post	patch	delete

Render a Partial

Step 1

Extract common view code into a partial template

partial file names are always prefixed with an underscore

example: _form.html.erb

example: app/views/layouts/_header.html.erb

Step 2

<%= render "name of partial without underscore" %>

render the partial from another view

example: <%= render 'form' %>

example: <%= render 'layouts/header' %>

Frequently Used Built-In View Helpers

```
truncate(text, options = {})
truncates the given text to a default of 30 characters
pluralize(count, singular, plural = nil)
pluralizes the singular word unless the count is 1
number_to_currency(number, options = {})
1234567890.50 => $1,234,567,890.50
number_to_percentage(number, options = {})
100 \Rightarrow 100.000\%
number_to_phone(number, options = {})
3035551212 => 303-555-1212
time_ago_in_words(from_time)
Time.now + 50.minutes => "about 1 hour"
content_tag(name, content, options = {})
```

returns a safe HTML tag of type name surrounding the content

Common Validation Methods

```
validates :name, presence: true
validates that the value of the specified attribute is not blank
validates :description, length: { minimum: 25 }
validates that the value of the specified attribute matches the specified length restrictions
validates :price, numericality: { greater_than_or_equal_to: 0 }
validates that the value of the specified attribute is numeric
validates :email, format: { with: /(\S+)@(\S+)/ }
validates that the value of the specified attribute has a format that matches the regular expression
validates :password, confirmation: true
validates that the value of the specified attribute matches a confirmation value
```

Common Validation Methods (cont.)

```
validates :how_heard, inclusion: { in: ["Blog", "Newsletter"] }

validates that the value of the specified attribute is available in the specified enumerable (array)

validates :role, exclusion: { in: ["Admin", "SuperUser"] }

validates that the value of the specified attribute is not available in the specified enumerable (array)

valid?

runs all the validations; automatically called when you try to create or save a model object
```

Populate the Database with Example Data

Step 1

```
example:
Event.create!(
    name: 'BugSmash',
    location: 'Denver',
    price: 0.00,
    starts_at: 10.days.from_now,
    description: 'A fun evening of bug smashing!'
)
```

Step 2

rails db:seed

loads the seed data in db/seeds.rb into the current environment's database

Adding RubyGems

Step 1

Add the gem (and optional version) to the Gemfile

```
gem 'bcrypt', '~> 3.1.7'
gem 'bootstrap', '~> 4.3.1'
```

Step 2

bundle install

installs any missing gems

Common Form Helper Methods

```
<%= form_for(@event) do |f| %>
```

generates a form for a single resource

<%= form_for([@event, @registration]) do |f| %>

generates a form for a nested resource

<%= f.label :name %>

returns a label tag for labelling an input field for the specified attribute

<%= f.text_field :name, autofocus: true %>

returns an input tag of the "text" type for accessing the specified attribute

<%= f.password_field :password %>

returns an input tag of the "password" type (masked) for accessing the specified attribute

Common Form Helper Methods (cont.)

```
<%= f.password_field :password %>
```

returns an input tag of the "password" type (masked) for accessing the specified attribute

```
<%= f.text_area :description, cols: 40, rows: 7 %>
```

returns a textarea tag set for accessing the specified attribute

```
<%= f.number_field :price %>
```

returns an input tag of type "number" for accessing the specified attribute

```
<%= f.datetime_select :starts_at %>
```

returns a set of select tags pre-selected for accessing the specified datetime-based attribute

```
<%= f.select :how_heard, ["Blog", "Newsletter"] %>
```

returns a select tag and a series of contained option tags for the specified attribute

Example has_many Methods

event.registrations

returns an array of the event's registrations (may be empty)

event.registrations.new(attributes = {})

instantiates a new registration for the event (event_id = event.id), but does not save it

event.registrations.create(attributes = {})

instantiates and saves a new registration for the event (event_id = event.id)

event.registrations << registration</pre>

associates the registration with the event (event_id = event.id) and saves the registration

event.registrations.size

returns the number of registrations associated with the event

event.registrations.delete(registration)

removes the registration from the event (if :dependent => :destroy, it will also delete the registration)

event.registrations.clear

removes all registrations from the event (if :dependent => :destroy, it will also delete the registrations)

Example belongs_to Methods

registration.event

returns the event associated with the registration (may be nil)

registration.event = an_event

assigns the event to the registration

Example belongs_to Methods

Single Resource

Nested Resource

/events

events_path

/events/:event_id/registrations

event_registrations_path(event_id)

/events/:event_id/registrations/new

new_event_path

new_event_registration_path(event_id)
